

# 2005 DOE Hydrogen Program Review

## Sulfur-Iodine Thermochemical Cycle

Paul Pickard  
Sandia National Labs  
May 25, 2005

# Overview

## Timeline

- Start - 9/2002
- Finish - 9/2008
- ~ 25% complete

## Budget

- Funding
  - DOE – 4.2 M\$
  - CEA In kind
- FY04 Funding – 1.4 M\$
- FY05 Funding – 2.8 M\$

## Barriers

- Materials – high temperature, corrosive environments
- Process chemistry, thermodynamic data
- Reactor to process interface

## Partners

- Process – CEA, SNL, General Atomics
- Supporting Technology – INL, ORNL, ANL, UNLV, MIT, UCB, Ceramatec

# Sulfur Iodine Thermochemical Cycle Objectives

- Investigate the potential of the Sulfur-Iodine cycle for Hydrogen production using nuclear energy
  - Flowsheet analysis of process options
  - Design and construct lab scale experiments for the three major reaction sections of the S-I cycle
    - *Lab scale experiments on  $H_2SO_4$  and  $HIx$  decomposition, and primary (Bunsen) reaction*
    - *Investigate process alternatives, materials, catalysts, diagnostics, membrane applications*
  - Utilize engineering materials where feasible
  - Integrate component sections and perform a closed loop experiment in final phase
  - Provide basis for pilot scale experiment design

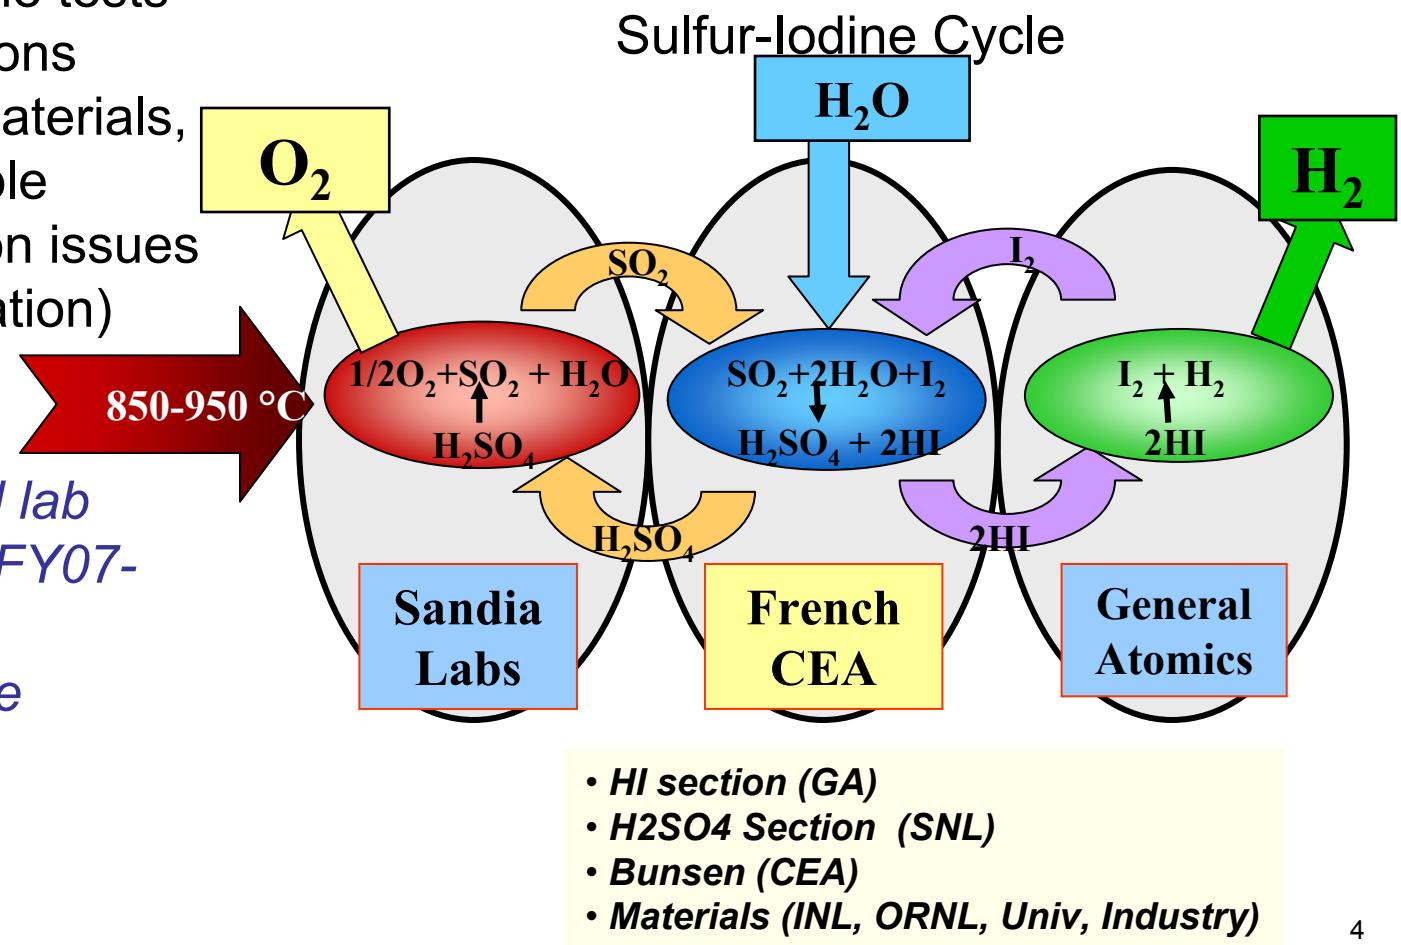

# Sulfur Iodine Thermochemical Cycle

## *Lab Scale Experiment – Approach*

- Perform flowsheet analyses of process alternatives
- Construct reaction sections using initial materials

- Perform stand alone tests on component sections
- Utilize improved materials, catalysts, as available
- Evaluate integration issues (controls, contamination)

- *Perform integrated lab scale experiments (FY07-FY08)*
- *Basis for pilot scale experiment design*

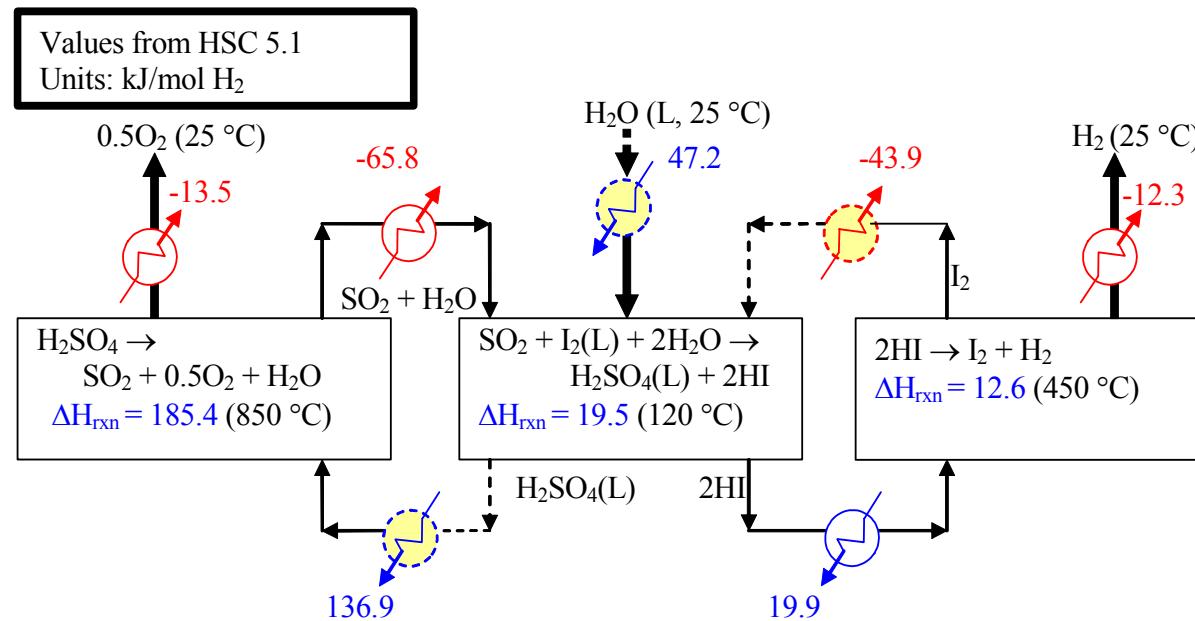

# Technical Accomplishments/ Progress/Results Summary

- Completed flowsheet analysis of alternate S-I configurations
- Designed and constructed test apparatus for component reactions ( $\text{H}_2\text{SO}_4$ ,  $\text{HIx}$ , Bunsen)
- Experiments initiated for component reaction sections
  - $\text{H}_2\text{SO}_4$  decomposition section (boiler, decomposer) engineering materials (started 12/2004, 850 C at ambient pressures)
  - Reactive distillation  $\text{HIx}$  decomposition section
    - Reactive distillation (started 2/2005, >20-35 bar, 250 C, glassware in pressure vessel)
    - Extractive distillation (started 4/2005)
  - Bunsen reactor section (started 2004, glassware exps, engineering materials apparatus, scheduled 9/2005, CEA)
- Thermophysical property measurements –  $\text{HI}/\text{I}_2/\text{H}_2\text{O}$  vapor-liquid equilibrium measurements initiated (CEA)
- Preliminary integrated lab scale experiment designs

# Flowsheet Analysis for Thermochemical Processes

- Simulate process configuration and conditions (ASPEN)
  - First step in process design, evaluation
  - Characterize process energy and stream flows (T, P,  $F_i$ )
  - Calculation of energy/heat requirements, efficiency

- Evaluation of process alternatives, uncertainties
  - System optimization, parameter studies
  - Some alternatives incorporated, others being evaluated experimentally
  - First step in defining component sizes and quantities -- costs

# Flowsheet Options for Laboratory Scale Sulfur-Iodine Sections

Process Section	Alternative 1	Alternative 2	Selection
<b>Section 1 (Bunsen)</b>	<b>Co-current Bunsen</b> <ul style="list-style-type: none"> <li>- Short residence time</li> <li>- Efficient HX</li> <li>- No side reactions</li> <li>- Previously demonstrated</li> </ul>	<b>Counter-current Bunsen</b> <ul style="list-style-type: none"> <li>- Fewer pieces of equipment</li> <li>- Fewer streams</li> <li>- Less recycle</li> <li>- Not yet demonstrated</li> </ul>	<b>Counter-current Bunsen</b> <ul style="list-style-type: none"> <li>- Less recycle, less complex, selected by CEA</li> </ul>
<b>Section II (<math>\text{H}_2\text{SO}_4</math>)</b>	<b>HP Flash/Vacuum Still</b> <ul style="list-style-type: none"> <li>- higher concentration ~90 mole % <math>\text{H}_2\text{SO}_4</math></li> <li>- less efficient</li> </ul>	<b>Direct contact HX</b> <ul style="list-style-type: none"> <li>- Direct contact heat /mass exchange</li> <li>- Heat required reduced ~5 to 10%</li> <li>- Eliminates vacuum still</li> </ul>	<b>Direct Contact HX</b> <ul style="list-style-type: none"> <li>- Reduced heat demand</li> <li>- <math>\text{SO}_3</math> recovery</li> </ul>
<b>Section III (<math>\text{HIx}</math>)</b>	<b>Extractive distillation</b> <ul style="list-style-type: none"> <li>- Use <math>\text{H}_3\text{PO}_4</math> or <math>\text{HBr}</math> to extract water</li> <li>- Vapor recompression (heat pumps) required for <math>\text{H}_3\text{PO}_4</math></li> <li>- <math>\text{HBr}</math> too costly under optimistic assumptions</li> <li>- Basic <math>\text{H}_3\text{PO}_4</math> steps demonstrated</li> </ul>	<b>Reactive Distillation</b> <ul style="list-style-type: none"> <li>- Less equipment, fewer streams</li> <li>- More recycle</li> <li>- heat pumps required</li> <li>- Not demonstrated</li> <li>- Similar heat and energy requirements</li> </ul>	<b>Reactive Distillation</b> <ul style="list-style-type: none"> <li>- Experiment baseline</li> </ul> <b><math>\text{H}_3\text{PO}_4</math> Extractive distillation</b> <ul style="list-style-type: none"> <li>- Backup process</li> </ul>

# Sulfuric Acid Section

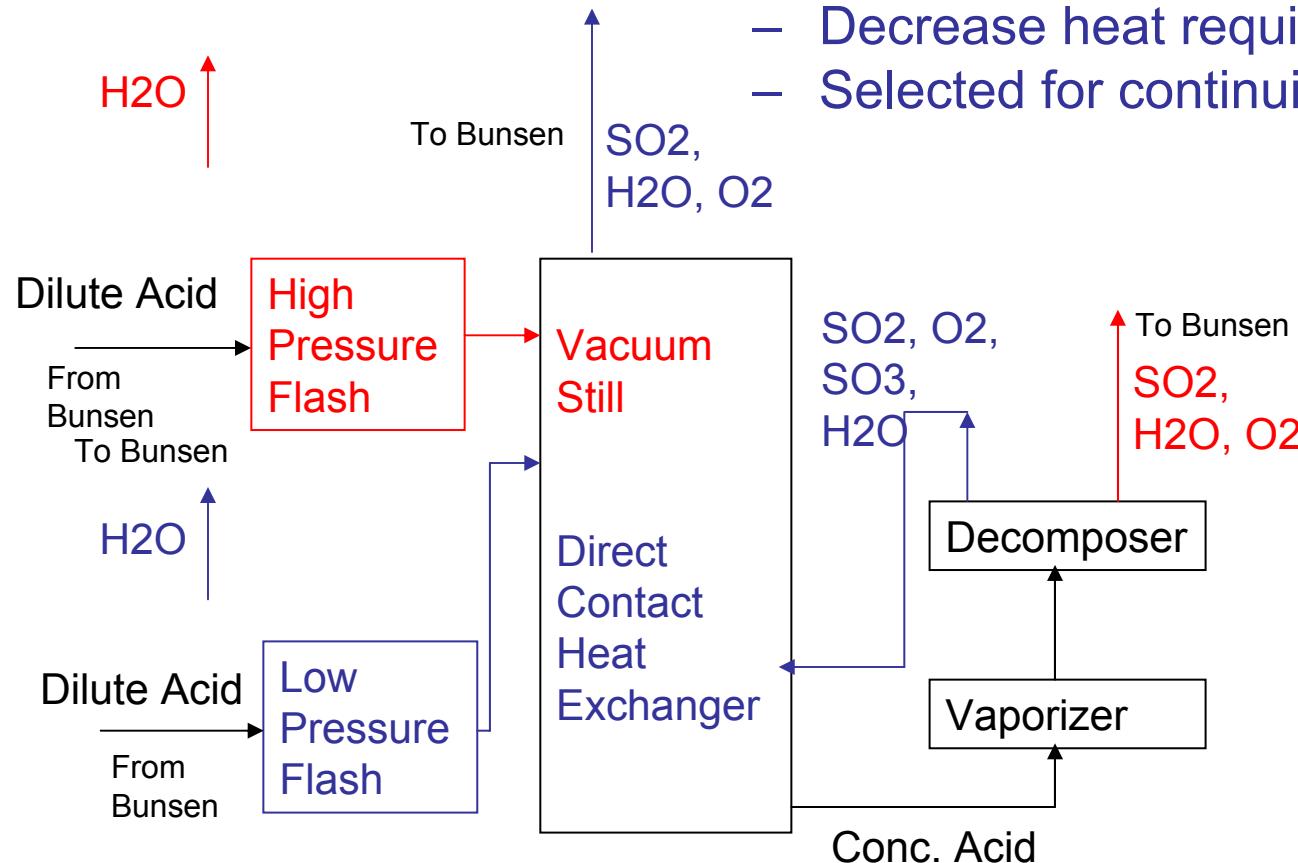

1. $2\text{H}_2\text{O} (\text{l}) + \text{SO}_2 (\text{g}) + \text{I}_2 (\text{l}) \rightarrow \text{H}_2\text{SO}_4 (\text{l}) + 2\text{HI} (\text{l})$	120 C
2a. $\text{H}_2\text{SO}_4 (\text{l}) \rightarrow \text{H}_2\text{O} (\text{g}) + \text{SO}_3 (\text{g})$	~500 C
2b. $\text{SO}_3 (\text{g}) \rightarrow \text{SO}_2 (\text{g}) + 1/2\text{O}_2 (\text{g})$	~850 C
3. $2\text{HI} (\text{g}) \rightarrow \text{I}_2 (\text{l}) + \text{H}_2 (\text{g})$	~400 C

- Concentrate dilute acid from Bunsen reaction (1), decompose to  $\text{SO}_3$ , and  $\text{SO}_2$  and  $\text{O}_2$ .  $\text{SO}_2$  and  $\text{H}_2\text{O}$  input to Bunsen. Accounts for most of the thermal input requirement
- Key Issues
  - High temperature process heat exchanger(s)
  - Materials – corrosion, temperature, catalyst activity
  - Energy efficiency - recuperation
- Options
  - Vacuum distillation
  - Direct contact HX – more heat efficient, eliminates vacuum still
- Sequence / approach
  - Construct initial section from best estimate materials, catalysts
  - Develop diagnostics, refine design, materials,
  - longer term materials and ceramic component development

# H<sub>2</sub>SO<sub>4</sub> Decomposition Section Alternatives

- **Vacuum Distillation**

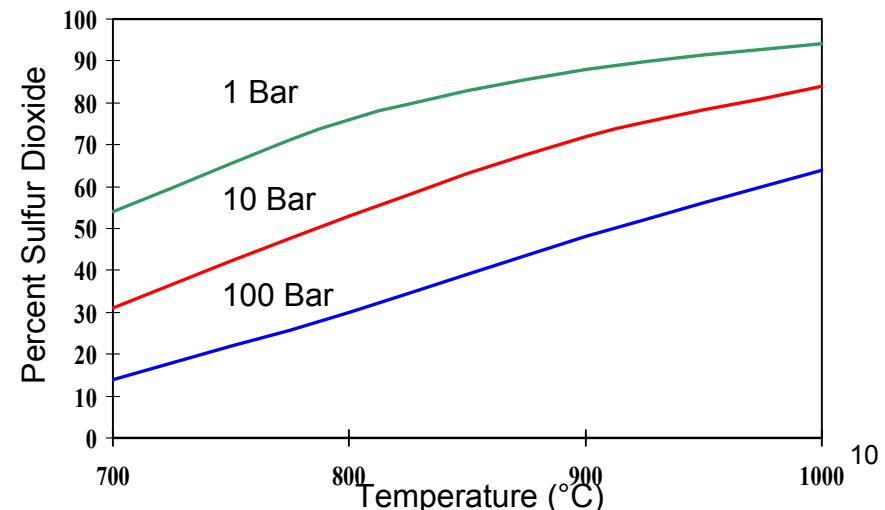

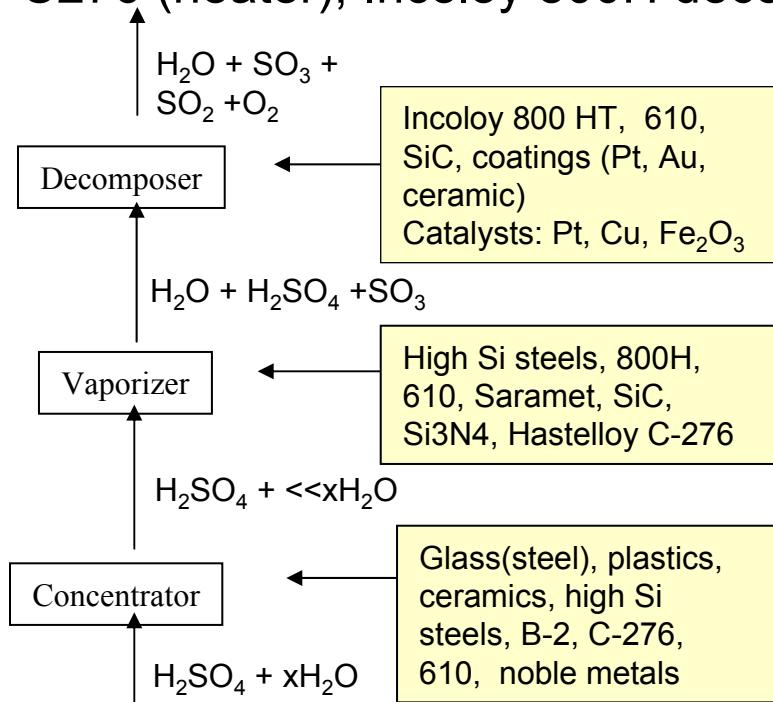

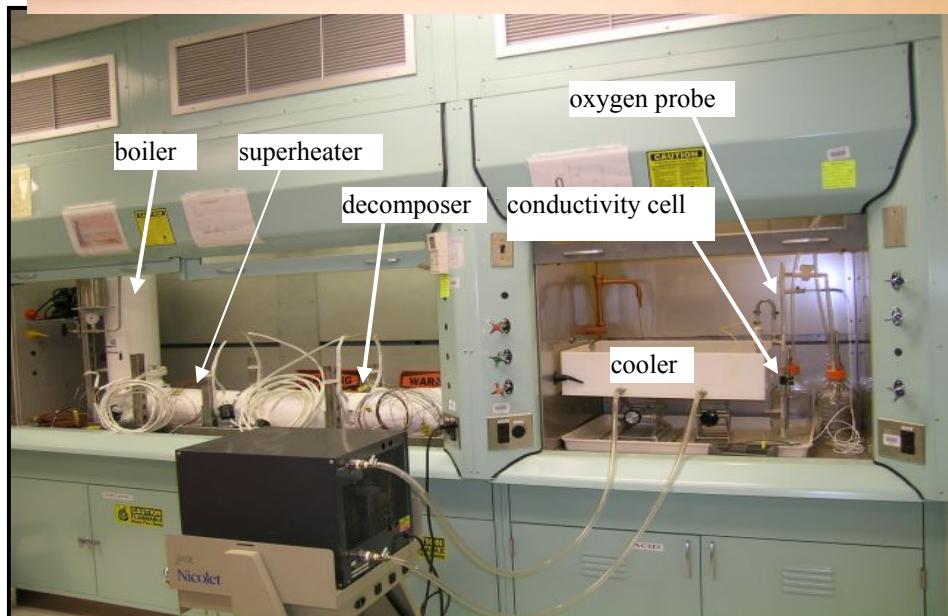

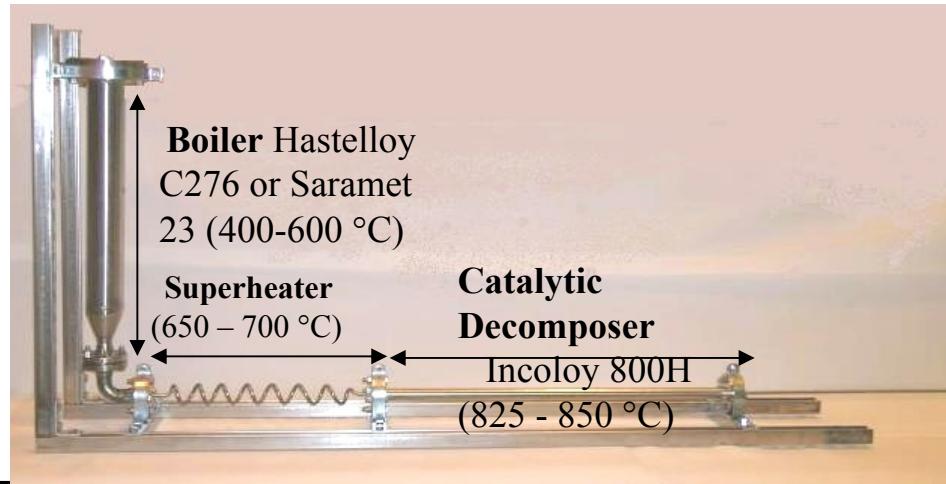

- Recover heat from high pressure flash to vacuum distillation

- **Direct Contact Heat Exchange**
  - Vacuum flash using low temperature waste heat
  - Additional concentration in high pressure DCHX recuperator
  - Decrease heat requirement
  - Selected for continuing work

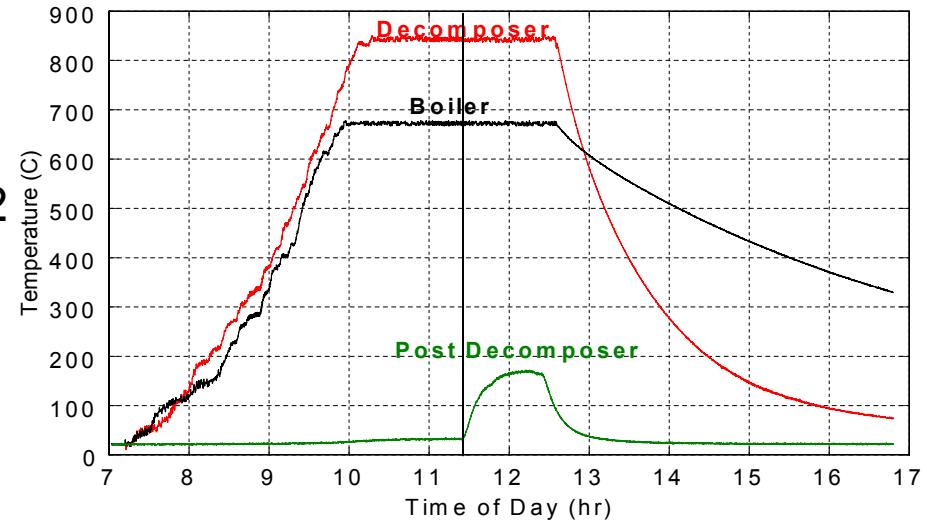

# Sulfuric Acid Section -- Status

- Completed construction of modular acid decomposition apparatus (Saramet boiler, Hastelloy C276 (heater), Incoloy 800H decomp.

# Sulfuric Acid Section -- Status

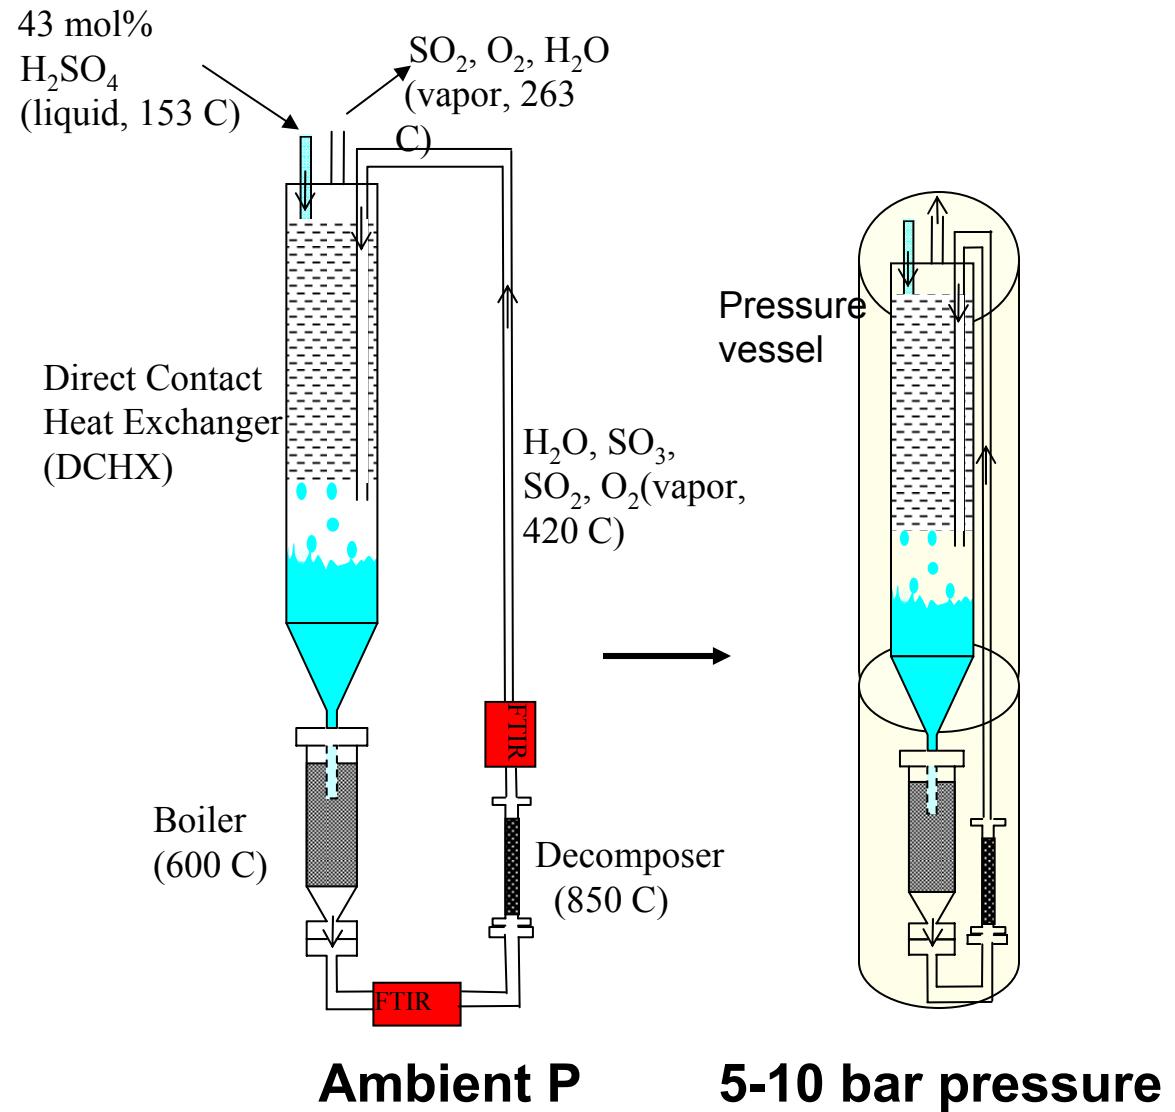

- Completed two acid tests at 850 C (ambient pressure)
- Limited corrosion in vapor phase and cold liquid sections
- Significant corrosion in boiling, condensing sections, qualitatively more severe than estimated static vs flow, SO<sub>2</sub>
- Boiler (ceramic bed) temperature increased to limit corrosion, straight-through configuration

Species	Corrosion Products	Incoloy 800H	Saramet 23	Hast. C276
Cr	10 g/L	21%	18%	16%
Ni	8.0 g/L	32%	17%	57%
Fe	6.6 g/L	40%	55%	5%
Si	0.042 g/L	<5%	5%	<0.08%
Mo	0.26 g/L		0.06%	16%
Au	0.0000046	0	0	0

# Sulfuric Acid Section – Testing Sequence

- 1.- Direct contact heat exchange (DCHX), glass DCHX, FTIR development
- 2.- DCHX – ambient pressure with concentrator
3. – DCHX, improved components (ceramics)
4. – Pressurized DCHX apparatus

# Section 3 – HI Decomposition

- Lower phase of Bunsen reaction is a mixture of HI - I<sub>2</sub> - H<sub>2</sub>O. This Section separates HI and decomposes it into H<sub>2</sub> and I<sub>2</sub>

- Key Issues

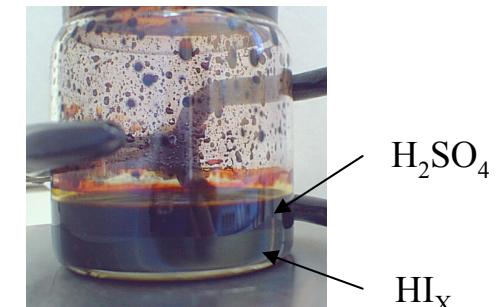

- Reactive distillation process chemistry
  - Uncertainty in HI/I<sub>2</sub>/H<sub>2</sub>O vapor equilibrium data
  - High recycle water volumes
  - Materials – corrosion, catalysts

- Options

- Reactive (baseline), Extractive (backup)

- Sequence / approach

- Evaluate both approaches experimentally, construct initial sections in glassware in pressure vessel (~20-40 bar)
  - Selection May 2005
  - Construct selected section based on best available materials, modify as improved materials tested

## Extractive Distillation

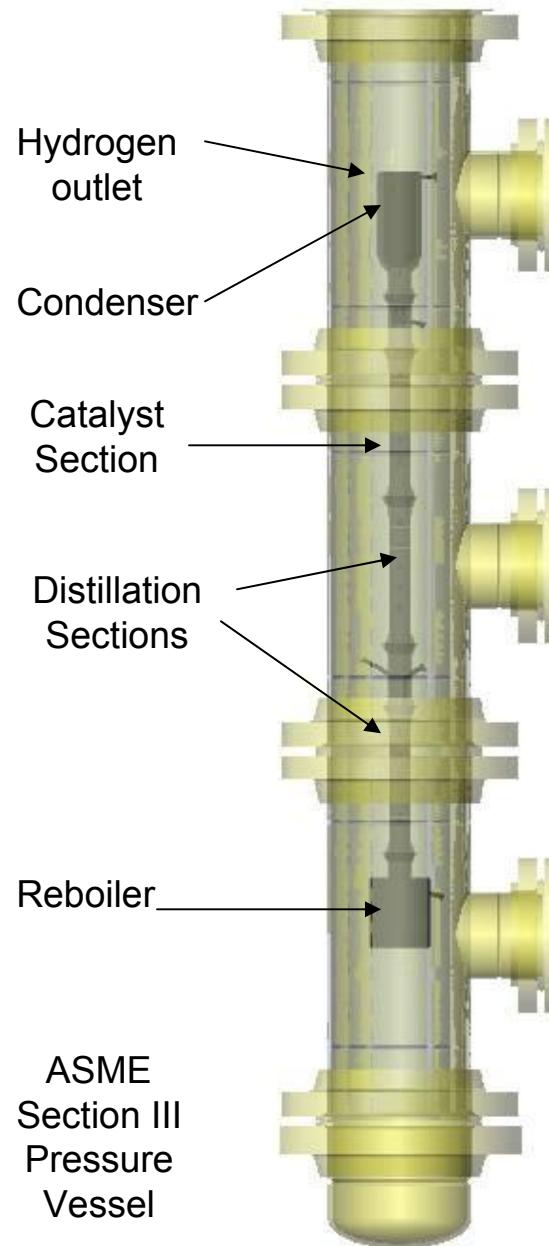

- Process steps demonstrated, not as integrated process
- Extractant rate and concentration limits not established

## Reactive Distillation

- Not demonstrated, reactivity of HI under req'd conditions unknown
- Catalyst performance must be determined – rate, deactivation
- Thermophysical data needed

# Initial Reactive Distillation Experiments are in Glass/Metal System

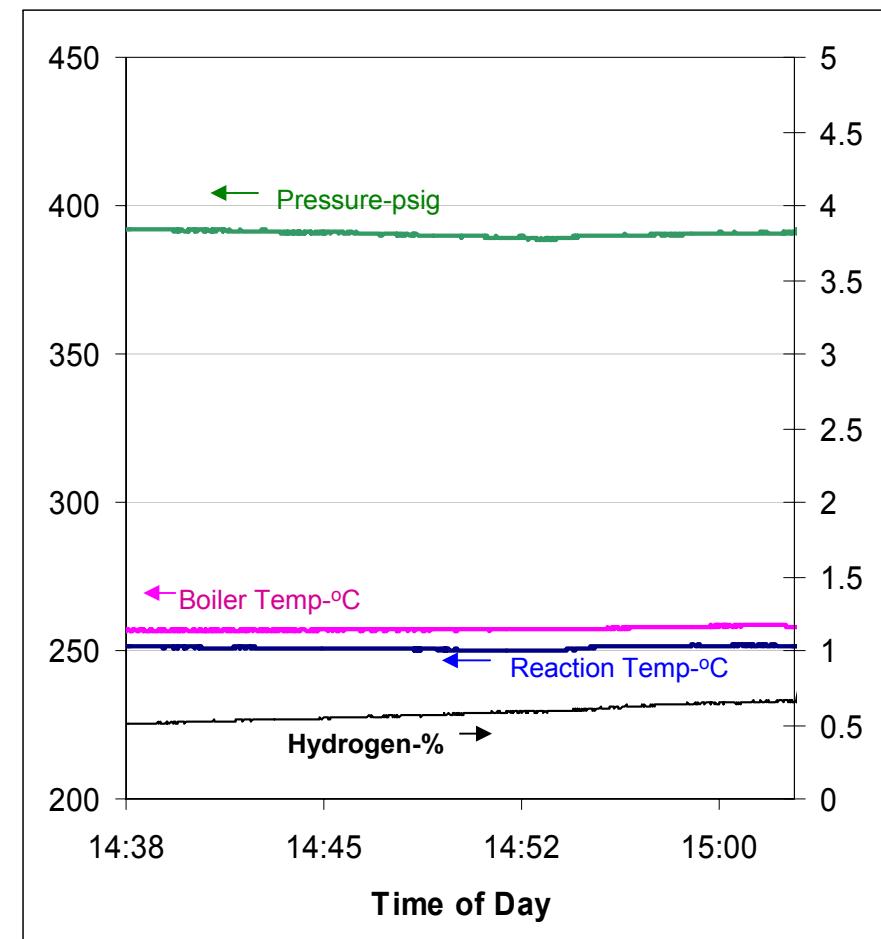

- Process operates at 300-600 psi, 250-300°C
- Distillation separates HI/H<sub>2</sub>O from I<sub>2</sub>
- HI decomposes on catalyst
- Reflux from condenser (HI/H<sub>2</sub>O) washes I<sub>2</sub> from catalyst
- Metallic pressure vessel rated at 625 psig
- Commercial glass distillation column is inexpensive
- Activated carbon catalyst under test
- Hydrogen measured continuously

# Reactive Distillation Results to Date

- Pressure balance system for glass equipment in pressure vessel works well
- Initial HI decomposition experiments begun
  - Focus on reaction kinetics
  - Additional run time required for catalyst life evaluation
- Hydrogen production has been demonstrated
- Lower than expected H<sub>2</sub> production is likely due to slow kinetics and poor catalyst performance

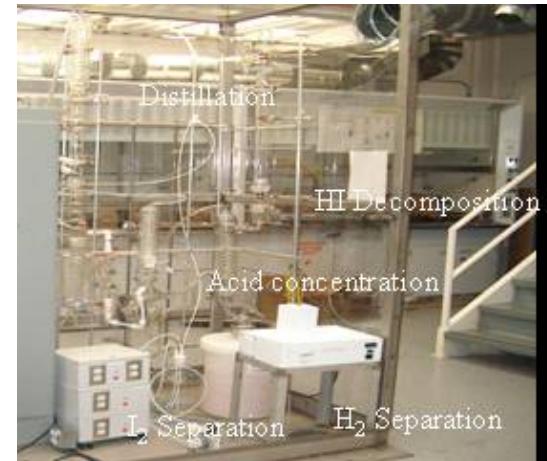

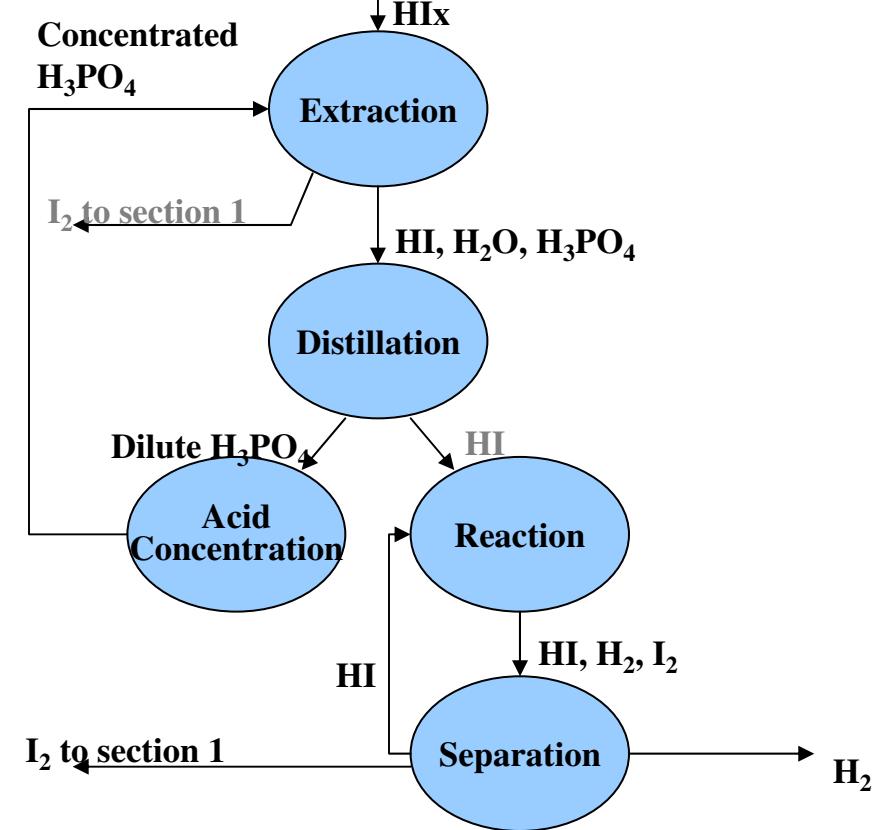

Operating conditions and H<sub>2</sub> production

# Extractive Distillation Experiments

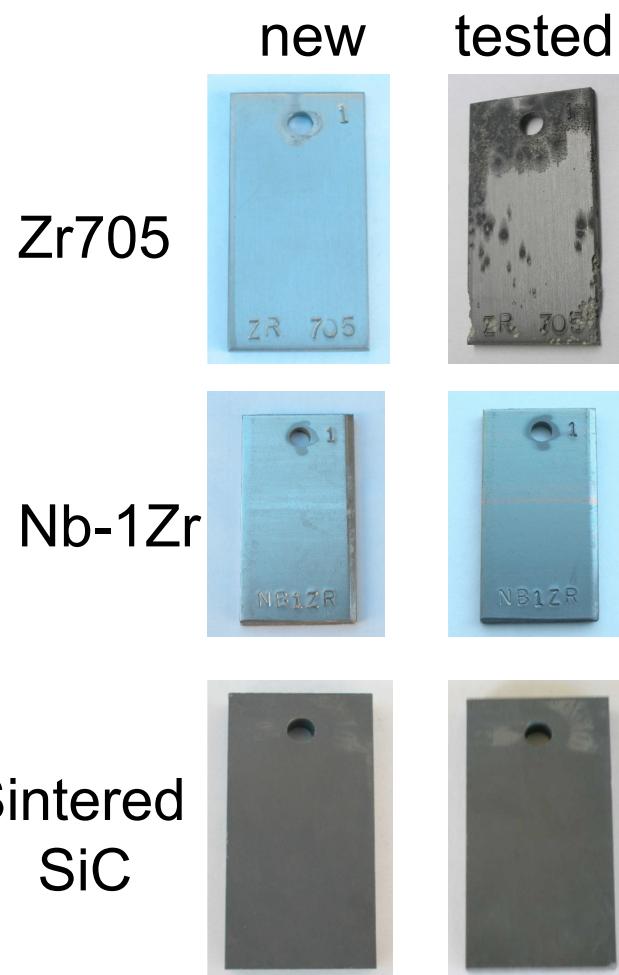

## Initial Experiments Done in Glass System

- Process operates at ambient pressure and 120-450°C
- HI/H<sub>2</sub>O absorbs into the phosphoric acid
- A separate, heavy I<sub>2</sub> phase is formed and returned to the Bunsen reaction
- H<sub>3</sub>PO<sub>4</sub> breaks the HI/H<sub>2</sub>O azeotrope to allow separation of HI from H<sub>2</sub>O and H<sub>3</sub>PO<sub>4</sub>
- Pure HI is decomposed to H<sub>2</sub> and I<sub>2</sub> in a carbon catalyst bed
- Status
- Flowsheet simulations completed and used for design of components
- Apparatus assembled and testing started
- April start, support May 15 decision on method for Lab scale exps.

# Materials Testing for HIx Section

**Refractory metals and ceramics have shown the best corrosion performance to date**

## HIx materials testing (UNLV and GA)

- 22 coupons from four classes of materials: refractory and reactive metals, superalloys and ceramics, have been screened.

Excellent	Good	Fair	Poor
Ta-40Nb, Nb-1Zr, Nb-10Hf, SiC(CVD), SiC(Ceram atec sintered), Mullite	Ta, Ta- 10W, Nb, Nb-7.5Ta, SiC (sintered) Si-SiC (3 kinds)	Mo-47Re, Alumina	Mo, C-276, Haynes 188, graphite*, Zr702, Zr705

\* structurally sound but absorbed HIx

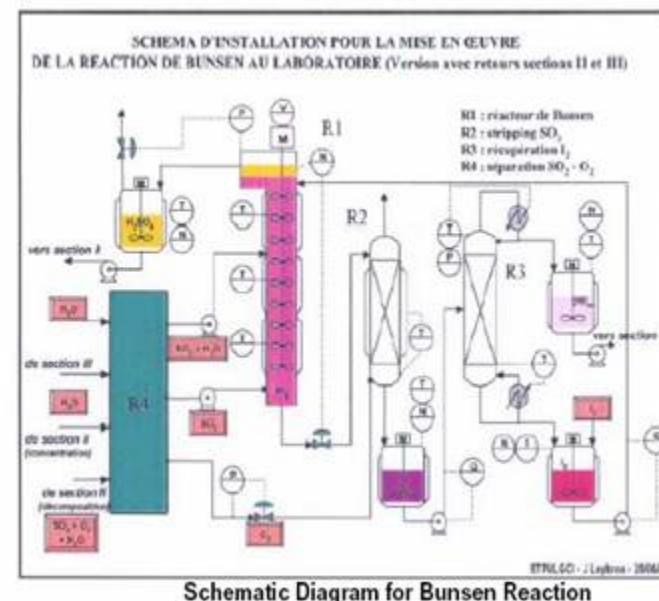

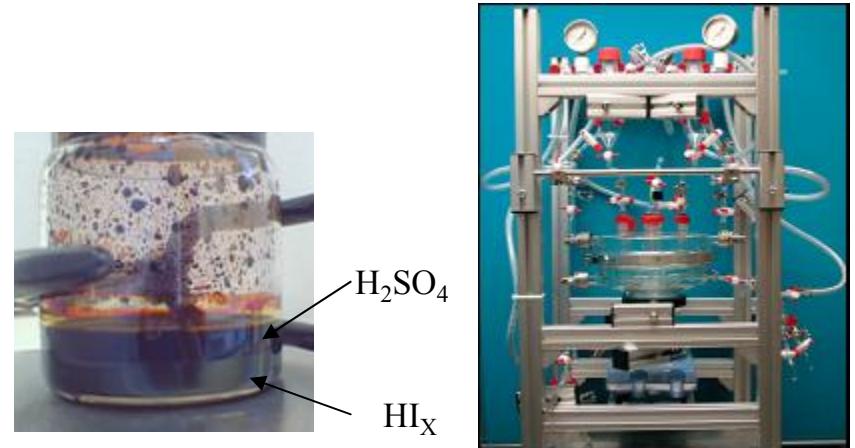

- Long term corrosion performance testing has started
  - effect of HI<sub>x</sub> on stress corrosion
  - cost reduction through cladding

# Bunsen Reaction Section (CEA)

- Bunsen reaction (formation of the two acids in aqueous phases) in optimal conditions for S-I process
- Key Issues
  - Thermal management in reaction column (S formation)
  - Recycle volumes from HI section
  - Thermophysical data uncertain (HI/I<sub>2</sub>/H<sub>2</sub>O -VLE)
  - Materials – corrosion
- Options
  - Co-current (demonstrated), Counter-current (simpler hardware, thermal mgt TBD)
- Sequence / approach
  - Construct glass reactor to determine elemental concentrations in liquid phases
  - Preliminary design of Bunsen section completed
  - First corrosion tests done.

# Bunsen Reaction Section - Status

- Initial Bunsen section exps
- Elemental measurements for determination of total amount of H<sup>+</sup> ions, sulphur and iodine in each phase
- Corrosion tests performed to select appropriate materials
- Preliminary design of Bunsen section
- Complete flowsheet analysis of Bunsen, HI<sub>x</sub> section options
- Complete construction of counter-current reactor – 9/05

# Supporting Technology Activities

- Materials – high temperature corrosion and mechanical properties – metals, ceramics (UNLV, GA, MIT, ORNL)
- High temperature systems interface – innovative heat exchanger designs, analysis (UNLV, UCB, Ceramatech)
- Membranes – high temperature inorganic membranes for acid decomposition (ORNL)
- $\text{SO}_3$  decomposition - electrolysis (ANL)
- Membranes for water separation (INL)
- Acid decomposition - catalysts (INL)

# Sulfur Iodine Thermochemical Cycle

## Planned Activities (FY05-FY08)

- FY05 – Complete component reaction section preparations and initial testing
  - Complete acid decomposer ambient pressure tests, construct high pressure apparatus
  - Select HIx distillation method for lab scale tests, construct HIx section
  - Complete Bunsen reactor construction
- FY06 – Complete testing of three stand alone sections in preparation for integrated lab scale experiments
- FY07 – Assemble component sections, initiate closed loop testing
- FY08 – Perform S-I Hydrogen test program in integrated lab-scale apparatus

# Publications and Presentations

## Sulfur Iodine Thermochemical Cycle

### **Presentations**

# Hydrogen Safety

**What is the most significant hydrogen hazard associated with this project?**

- The most significant hydrogen hazard is associated with a hydrogen explosion from the HI decomposition experiments.
- This could happen if hydrogen accumulates in large quantities in the equipment or the exhaust system and an ignition source is present.

# Hydrogen Safety

## What are you doing to deal with this hazard?

- Work is governed by General Atomics corporate safety program
- Requires development and approval of a Hazardous Work Authorization (HWA) before any experimental work can be initiated.
- Approval is given by independent Safety Committee, after detailed review of the HWA document.
- HWA details hazards and mitigation techniques. (Requirements include applicable Government and industry regulations).
  - Equipment designed to minimize the free hydrogen volume
  - Work performed in inerted environment.
  - Providing for air and Nitrogen dilution of hydrogen exhaust ports to keep the hydrogen concentration well below the explosive limit.
  - Equipment designed to eliminate potential ignition sources
  - Burst disc installed that vents into the chemical scrubber
